## Introduction

Legislation is in place to control emissions from various pollutant processes *i.e.* the Waste Incineration Directive (WID) regulates activities that involve burning or gasification of waste (Figure 1)

Technologies have been developed which react a reductant with NO<sub>x</sub> emissions, forming harmless N<sub>2</sub> and H<sub>2</sub>O. Development of a material and process to treat NO<sub>x</sub> emissions using H<sub>2</sub> is the aim of this project

Utilising H<sub>2</sub> already present in the system (Figure 1) could provide a reductant which does not have to be specially manufactured (in contrast to *e.g.* NH<sub>3</sub>, urea), and hence would be a cleaner approach

H<sub>2</sub> can also be used in NO<sub>x</sub> storage and reduction (NSR) processes where NO<sub>x</sub> species are first 'trapped' and subsequently reduced through alternate lean and rich-burn cycles (Figure 2)

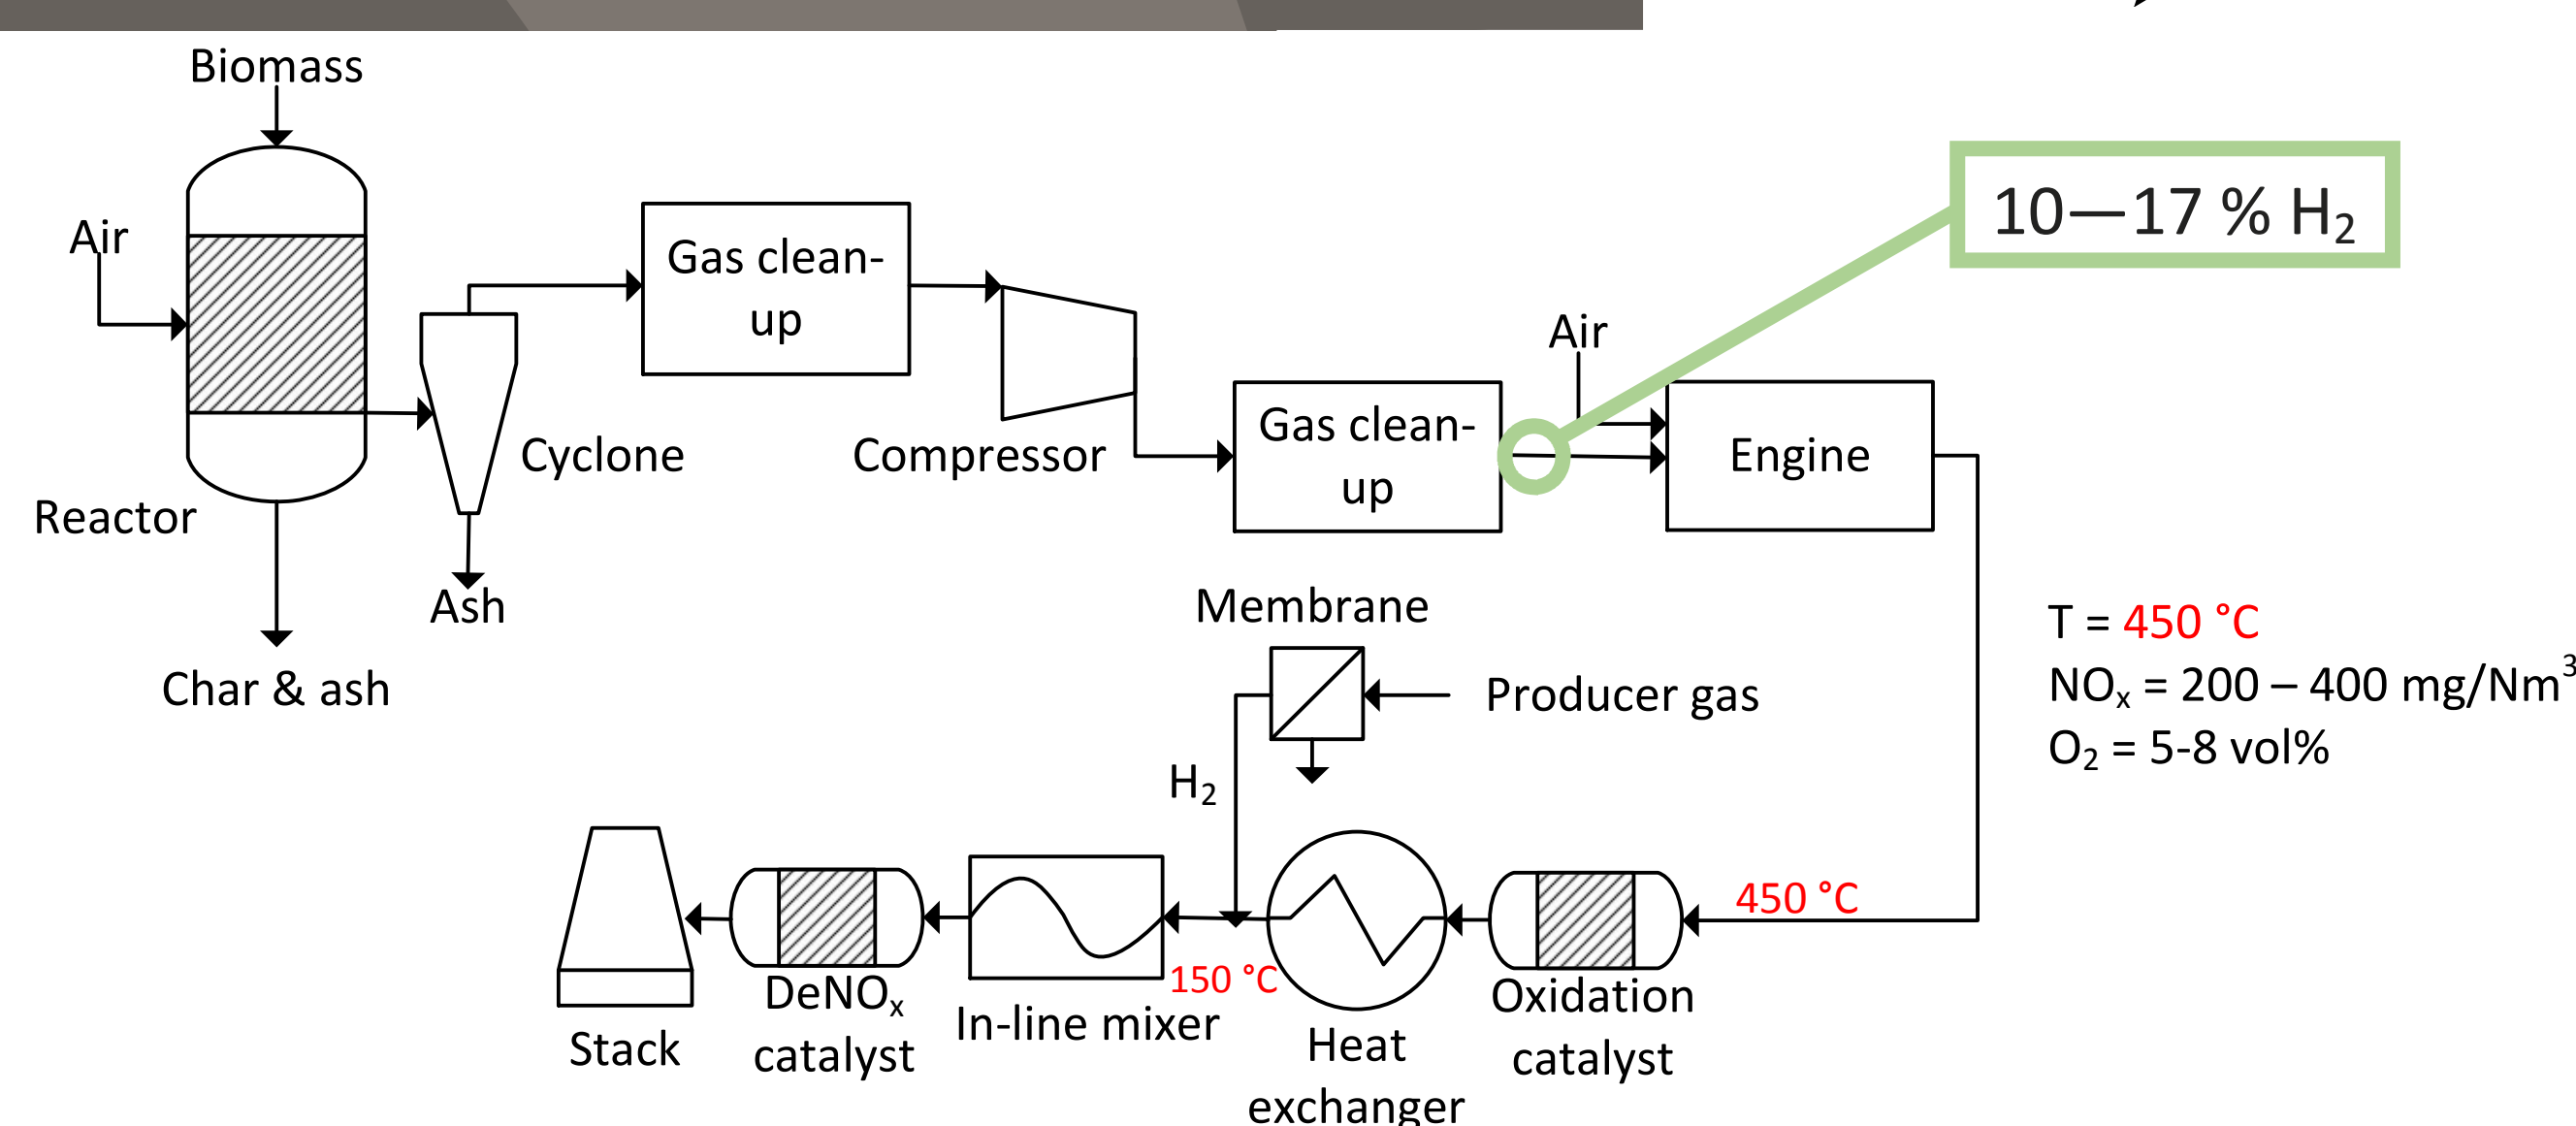

Figure 1: Schematic of proposed biogas engine exhaust treatment system

## Theory

Pt/Ba/Al<sub>2</sub>O<sub>3</sub> is considered the 'standard' NSR catalyst and has been extensively studied for this process since original publication by Takahashi *et al.* (1996). As such, the chemical processes involved during NSR cycles are well understood

NSR catalysts generally consist of a noble metal and 'storage component' (alkaline earth metal) supported on alumina. Operating through alternate lean and rich conditions, the NO<sub>x</sub> is initially 'stored' on the catalyst surface during lean conditions (Figure 2), in the form of nitrates and nitrites. Subsequent introduction of a reductant, in this case H<sub>2</sub>, reduces the stored species to form N<sub>2</sub>. Although silver catalysts have previously been explored for related deNO<sub>x</sub> applications, primarily in Selective Catalytic Reduction (SCR) approaches (*e.g.* Burch *et al.* (2004), their performance in NSR reactions has not been reported

## Experimental

Table 2: NSR Experimental Conditions

Phase	Lean	Rich
Composition	1000 ppm NO, 3.3 % O <sub>2</sub> , N <sub>2</sub>	2500 ppm H <sub>2</sub> , N <sub>2</sub>
Total Flow Rate (ml/min)	480	550

Table 3: Temperature-programmed Desorption (TPD) Experimental Steps

Step 1	Heat to 500 °C under N <sub>2</sub>
Step 2	Reduce in 8000 ppm H <sub>2</sub> /N <sub>2</sub> for 30 mins
Step 3	Pre-oxidize in 10 % O <sub>2</sub> /N <sub>2</sub> for 15 mins
Step 4	Cool down to 150 °C in N <sub>2</sub>
Step 5	1000 ppm NO/N <sub>2</sub> for 30 mins
Step 6	Heat to 700 °C in N <sub>2</sub> at 10 °C/min

## Catalysts

Catalysts prepared using impregnation techniques and supported on honeycomb monoliths (Figures 3 & 4)

Table 1: Catalyst Compositions

Silver	Loading (wt%)	
	Storage Component	
	Barium	Potassium
5	14	-
5	-	38

Figure 3: Ag/Ba/Al<sub>2</sub>O<sub>3</sub> monolith catalysts

Channel Size = 1 mm x 1 mm (~80 channels per monolith)

Figure 4: Ag/K/Al<sub>2</sub>O<sub>3</sub> monolith catalysts

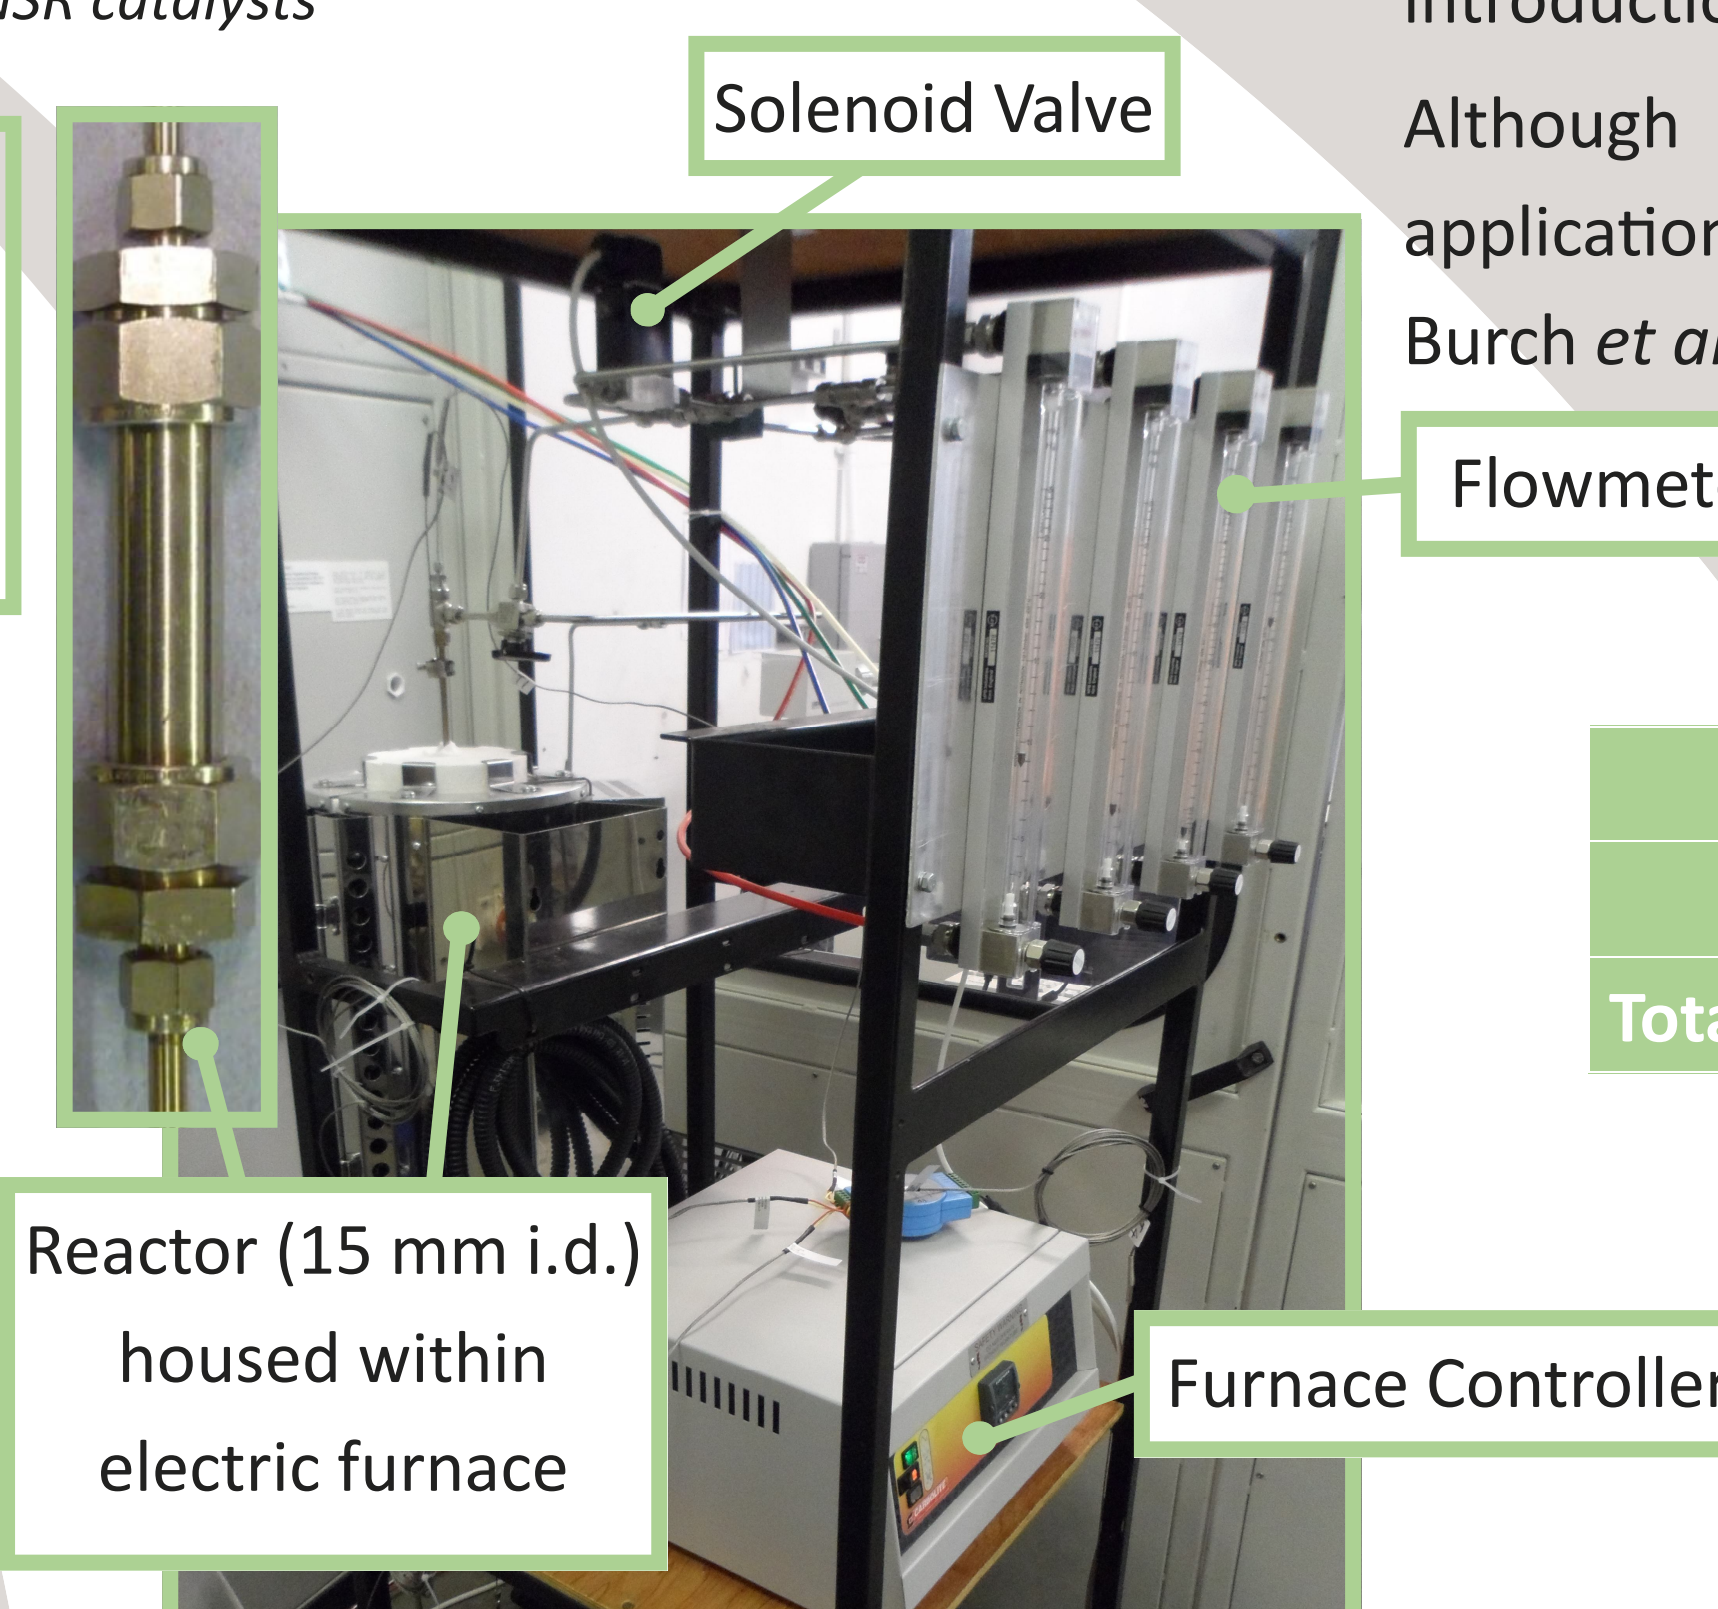

Figure 5: Photo of experimental set-up

## Results

Figure 6: H<sub>2</sub>-NSR Lean and Rich cycle over Ag/Ba/Al<sub>2</sub>O<sub>3</sub> catalyst at 400 °C

Figure 7: NO-TPD over Ag/Ba/Al<sub>2</sub>O<sub>3</sub> and Ag/K/Al<sub>2</sub>O<sub>3</sub> catalysts

Figure 8: H<sub>2</sub>-NSR Lean and Rich cycle over Ag/K/Al<sub>2</sub>O<sub>3</sub> catalyst at 400 °C

## Conclusions

Both catalysts appear to demonstrate some potential in their ability to 'store' and subsequently reduce NO (Figures 6 and 7). Ag/K offers a greater storage capacity (which may be related to storage component loading) and less formation of side products. Ag/Ba demonstrates a greater ability to reduce the stored NO<sub>x</sub> with minimal NO desorption seen in the rich phase. Both catalysts demonstrate different affinities for NO (Figure 7), with Ag/K demonstrating reaction of surface species with NO, even in the absence of O<sub>2</sub>: formation of N<sub>2</sub>O (+1200 ppm) and NO<sub>2</sub> at higher temperatures

## Future Work

Complete catalyst characterization including Temperature-programmed Surface Reaction (TPSR) studies

Investigate possible impact of 'KK leaves' Al<sub>2</sub>O<sub>3</sub> support structure (Figure 9); freeze drying process produces thin leaves of Al<sub>2</sub>O<sub>3</sub> (thickness 0.2-0.8 μm), first reported by Kolaczowski *et al.* (2006). The thin layer structure may offer less resistance to diffusion, possibly impacting the quantity of catalyst required
